Abstract

Twitter has acted as an important source of information during disasters and pandemic, especially during the times of COVID-19. In this paper, we describe our system entry for *WNUT 2020 Shared Task-3*. The task was aimed at automating the extraction of a variety of COVID-19 related events from Twitter, such as individuals who recently contracted the virus, someone with symptoms who were denied testing and believed remedies against the infection. The system consists of separate multi-task models for slot-filling subtasks and sentence-classification subtasks while leveraging the useful sentence-level information for the corresponding event. The system uses COVID-Twitter-Bert with attention-weighted pooling of candidate slot-chunk features to capture the useful information chunks. The system **ranks 1st** at the leader-board with **F1 of 0.6598**, without using any ensembles or additional datasets. The code and trained models are available at this [https url](https://github.com/Ayushk4/extract_covid_entity)¹.

1 Introduction

COVID-19 was declared a global pandemic by the World Health Organization on March 11, 2020. As of 2020/09/21, there are over 30 million cases² and 900,000 deaths due to the infection. With the imposed lock down, work from home and physical distancing, social media like twitter saw an increased usage. A large part of usage was posting and consuming information pertaining to the novel infection. These information include potential reasons for contraction of the disease, such as via exposure to a family member who tested positive, or someone who is showing COVID symptoms

but was denied testing. Accompanying to the pandemic was an infodemic of misinformation about COVID-19, including fake remedies, treatments and prevention-suggestions in social media.([Alam et al., 2020](#)).

[Zong et al. \(2020\)](#) show the possibility to automatically extract structured knowledge on events related to COVID-19 from Twitter and released a dataset of COVID related tweets across 5 event types. We used this dataset in our experiments for the shared-task. These tweets are annotated for whether they belong to an event (we refer this as **corresponding event** subtask in this paper) and their event-specific questions (factual or opinion). We identify these event-specific question into two types of subtasks, namely **slot-filling** and **sentence classification**.

Our system consists of separate multi task models for slot-filling subtasks and sentence-classification subtasks. Our contribution comprises improvement upon the baseline (mentioned in section 2) in three ways:

- We incorporate the corresponding event subtask as auxiliary subtask and fuse its features for all the event-specific subtasks.
- We perform an attention-weighted pooling over the candidate chunk span enabling the model to attend to subtask specific cues.
- We use the domain specific Bert of Covid-Twitter Bert ([Müller et al., 2020](#)).

2 Related Works

Sentence classification tasks (such as opinion or sentiment mining) as well as slot-filling tasks have greatly progressed with deep learning advancements such as LSTM ([Hochreiter and Schmidhuber, 1997](#)), Tree-LSTM ([Tai et al., 2015](#)) and transfer learning over pre-trained models ([Peters](#)

^{*} Authors in lexicographic order, equal contributions.

²<https://coronavirus.jhu.edu/map.html>

et al., 2018; Howard and Ruder, 2018; Devlin et al., 2019). Among these, CT-Bert outperforms others on COVID related twitter tasks (Müller et al., 2020). Taking inspiration from the same, we use CT-Bert as part of our architecture. A variety of slot-filling approaches have been built on top of these deep learning advancements (Kurata et al., 2016; Qin et al., 2019). The proposed baseline for our task (Zong et al., 2020) modifies Bert model for slot-filling task inspired by Baldini Soares et al. (2019). Due to the good performance offered by Bert (Devlin et al., 2019) and (Baldini Soares et al., 2019), we build upon this baseline approach.

Extraction of structured knowledge from tweets pertaining of events (Benson et al., 2011) has been studied for disaster and crises management (Abhik and Toshniwal, 2013; Rudra et al., 2018) and in pandemic scenarios (Al-Garadi et al., 2016). Extracting such entities can be useful for epidemiologists, deciding policies and preventing spread (Al-Garadi et al., 2016; Zong et al., 2020).

Due to the fast spreading nature of the infection, it is also difficult to manually trace spread of the pandemic. However, with twitter event-specific entity extraction and Geo-location, one could potentially build a real-time pandemic surveillance system (Lwowski and Najafirad, 2020; Al-Garadi et al., 2020). (Bal et al., 2020) show that health-issues related misinformation is prevalent in social media, while (Alam et al., 2020) talks about covid-specific misinformation. Such systems for extracting structured knowledge over the tweets talking about potential cure for COVID will help study how users perceive the COVID misinformation.

In §3 we describe the dataset and the problem statement. Then in §4 we discuss the details of our two multi-task models followed by experiments, results and conclusion.

3 Dataset and Problem statement

Now, we will briefly go over the dataset. The reader may refer (Zong et al., 2020) for full details. Each of the 7500 tweets in the dataset belongs to one of the 5 event types: tested-positive, tested-negative, can-not-test, death, and cure. The first four events aimed at extracting structured reports of coronavirus related events, such as self-reported cases or news stories about public figures who were exposed to the virus. Each tweet was first annotated for whether it belongs to its respective event (e.g. Is the tweet belonging to tested-positive event talking

Event	# Tweets
Tested positive	2397
Tested negative	1144
Denied testing	1128
Death	1231
Cure/Prevention	1244
Total	7144

Table 1: Dataset statistics, scraped during early July.

Tweet	Sigh of relief. My wife's COVID-19 test came back negative today. The Lord has been gracious. One of my favorite pics I took of her. #thankful.[URL]
Slot Filling	{Who}: My wife's, {Where}: Not Specified, {When}: today, {CloseContact}: Not Specified, {Age}: Not specified, {Duration}: Not Specified
Sentence Classify	{Relation}: Yes, {Gender}: Female
Corresponding Event	{Did someone test negative?} Yes

Figure 1: An example tweet from tested negative event.

about someone who tested positive?). Throughout this paper, we refer to this as the **Corresponding Event** subtask. The tweets that correspond to its event were then annotated for event-specific questions or **subtasks** about factual information and user's opinions. All annotations are done by multiple AMT with inter-annotation agreement. The event-specific questions or subtasks (e.g. name, age, gender of the person tested positive) varies depending on the event. These subtasks are of two categories: **slot-filling** (e.g., Who tested positive/negative?, Where are they located?, Who is in close contact with person contracting the disease?) and **sentence classification** (e.g. Is author related to infected person?, Does the author experience any symptoms?, Does the author believe a cure method is effective?).

The dataset released tweet IDs and its annotations. We obtain our text corresponding to tweets using the official Twitter API³. Table 1 shows the statistics for the dataset we scrapped in early July.⁴ Figure 1 shows an annotated example from the dataset. The event-specific subtasks were identified into two categories shown in Table 2.

We now formally describe the two types of event-specific subtasks:

Slot-filling subtasks: Assume n slot-filling subtasks $\{S_1, S_2 \dots S_n\}$. We set up each slot-filling sub-

³<https://developer.twitter.com/>

⁴We get about 350 fewer tweets than the corpus. Some tweets are not obtainable over time as the accounts/tweets get deleted, renamed, banned, or change-visibility etc.

Event	Sentence Classification	Slot-Filling task
Tested positive	gender, relation	who,age,recent-visit,when,where,employer,c.-contact
Tested negative	gender, relation	who,age,when,where,duration,close-contact
Denied testing	relation, symptoms	who,when,where
Death	relation, symptoms	who,age,when,where
Cure	opinion	what is the cure, who is promoting cure

Table 2: The proposed event-specific subtasks split into two subtask types: slot-filling and sentence classification

task S_i as a supervised binary classification problem. Given the tweet t and the candidate slot s , the model $f(t, s) \rightarrow \{0, 1\}$ predicts whether s answers its designated question. A list of candidate slot of all noun chunks and name entities is extracted by a Twitter tagging tool (Ritter et al., 2011) same as the baseline.

Sentence classification subtasks: Assume m sentence classification subtasks $\{C_1, C_2 \dots C_m\}$. Given a sentence classification subtask C_i aims to learn a model $g(t) \rightarrow \{l_1, l_2 \dots l_k\}$, where t is a tweet and l_j is a label. Here the number of labels can vary depending on the subtask, for example gender is labelled with {Male, Female, Others/Not Specified}, Relation with {Yes, No}, Opinion with {effective, no cure, not effective, no opinion} and so on. All these subtasks are ‘supervised’ classification problems

The dataset is also annotated with whether a tweet corresponds to its respective event or not. We treat this as an additional **Corresponding Event subtask**. This is a binary classification task that aims to learn a model $h(t) \rightarrow 0, 1$ where t is a tweet.

4 Approach

In the subsection §4.1 we describe the multi-task model for slot-filling. In the subsection §4.2 we describe the multi-task model for sentence-classification.

4.1 Slot-filling

We improve upon the baseline (Zong et al., 2020) by using domain specific Bert, use attention-weighted pooling over the candidate chunk feature sequence, incorporate auxiliary Corresponding Event subtask and utilize its logits for all the slot-filling subtasks. Now, we first describe the Bert baseline followed by our approach. Our slot-filling model can be seen in Figure 2.

The baseline consists of Bert (Devlin et al., 2019) based classifier. It takes a tweet t as input and en-

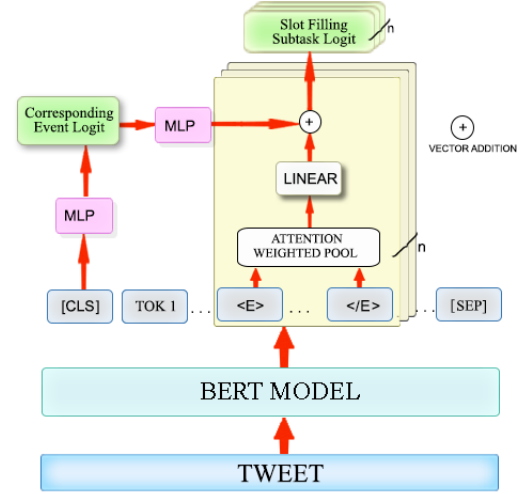

Figure 2: Slot-Filling Model, described in Section §4.1. Here n is the number of slot-filling subtasks.

closes the candidate slot s , within the tweet, inside special entity start $< E >$ and end $< /E >$ markers. The Bert hidden representation of token $< E >$ is then processed through a fully connected layer with softmax activation to make the binary prediction for a task (Baldini Soares et al., 2019). Since many slot-filling tasks within an event are semantically related to each other, they jointly trained the final softmax layers of all the subtasks S_i in an event by sharing their Bert model parameters.

COVID Twitter Bert (CT-Bert) is a Bert-Large model pretrained on Twitter Corpus on COVID-19 topics, leading to marginal improvements from Bert on tasks based on Twitter datasets (Müller et al., 2020). This motivates us to use CT-Bert instead of Bert from the baseline model.

In the baseline, the Bert hidden representation of token $< E >$ is used for classification. Here, however, we use attention-weighted pool of the CT-Bert hidden representation of tokens between $< E >$ and $< /E >$ (both inclusive). Formally, let $\{x_0, \dots x_p, \dots x_q, \dots x_n\}$ be the output vectors from

hidden representation of CT-Bert where p and q are indices of $\langle E \rangle$ and $\langle /E \rangle$ respectively, then for any of the slot-filling subtask S_j , we get its pooled vector as follows:

$$\tilde{x}^{S_j} = \sum_{i=p}^q \alpha_i^{S_j} x_i$$

$$\alpha_i^{S_j} = \text{Softmax}_{p \text{ to } q}(x_i^T a^{S_j})$$

where x_i^T denotes the transpose of x_i , a^{S_j} is a trainable vector. The motivation for attention weighted pooling is that depending on the task, model can attend to different portions of the candidate slot chunk. Next we obtain the binary classification score vector:

$$h^{S_j} = W^{S_j} \tilde{x}^{S_j} + b^{S_j} \quad (1)$$

Here W^{S_j} and b^{S_j} are trainable parameters.

We treat the Corresponding Event subtask as an auxiliary task and then fuse its logits to each of the other slot-filling subtasks. The motivation is that a task-specific entity for any event shall be present in a tweet only if the tweet belongs to its respective event.

To predict the label for Corresponding Event subtask, we take the CT-Bert features of $[CLS]$ token and pass it through a MultiLayer Perceptron (MLP) to get logits h_{ces} .

We fuse h_{ces} prediction over each subtasks S_j by adding it to h^{S_j} (from (1)) to get the logits $h_f^{S_j}$:

$$h_f^{S_j} = h^{S_j} + \text{MLP}^{S_j}(h_{ces})$$

In practice, we share the parameters of the MLP^{S_j} across all the slot-filling subtasks S_j .

Given a tweet t and slot s , our loss for slot-filling model over n slot-filling subtasks $\{S_1, S_2 \dots S_n\}$ and Corresponding Event subtask looks like:

$$\begin{aligned} & \text{Loss}(t, s, y_{ces}, (y_1, y_2 \dots y_n)) \\ &= \lambda_1 \text{CE}_{\text{Loss}}(h_{ces}, y_{ces}) + \sum_{k=1}^n \text{CE}_{\text{Loss}}(h_f^{S_k}, y_k) \end{aligned}$$

where CE_{Loss} is softmax cross entropy loss, y_{ces} is ground truth label for Corresponding event subtask and $(y_1, y_2 \dots y_n)$ are the labels for the candidate slot s of tweet t for the subtasks $\{S_1, S_2 \dots S_n\}$. We keep $\lambda_1 = 1$.

Our preprocessing for this is same as baseline.

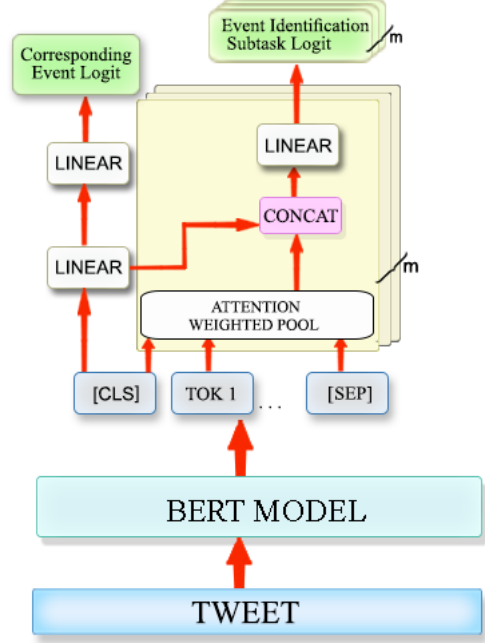

Figure 3: Sentence Classification model, described in section. §4.2. Here m is the number of Sentence Classification subtasks.

4.2 Sentence classification

Our Sentence classification model overview is present in Fig. 3. We use a Bert based (Devlin et al., 2019) sentence classifier and improve it by using CT-Bert, incorporating the auxiliary Corresponding Event subtask and attention-weighted pooling over entire sequence.

This model uses CT-Bert instead of Bert and Corresponding Event subtask as an auxiliary task for similar reasons as slot-filling subtask.

An attention-weighted pooling is done over the feature sequences from CT-Bert to extract the most recent information. Formally, let $\{x_0, x_1, \dots, x_n\}$ be the output vectors from CT-Bert (here 0 and n are indices of $[CLS]$ and $[SEP]$ respectively), then for any of the sentence classification subtask C_j , we get its pooled vector \tilde{x}^{C_j} as follows:

$$\tilde{x}^{C_j} = \sum_{i=0}^n \beta_i^{C_j} x_i \quad (2)$$

$$\beta_i^{C_j} = \text{Softmax}_i(x_i^T a^{C_j} + c^{C_j})$$

where a^{S_j} , c^{S_j} are trainable vector and scalar respectively.

For the Corresponding Event subtask, we take the CT-Bert vector representation of $[CLS]$ token

and pass it through an MLP. Assume the MLP’s final and hidden states to be v_{ces} and h'_{ces} .

Next we incorporate information from corresponding event subtask into sentence classification subtask C_j . Here we concatenate the hidden state features from the MLP of Corresponding Event Subtask h'_{ces} to pooled vector \tilde{x}^{C_j} from 2 to get the logits $h_f^{C_j}$ for each subtask S_j , as follows:

$$h_f^{C_j} = [\tilde{x}^{C_j}; h'_{ces}]^T W^{C_j} + b^{C_j}$$

Here T denotes transpose, $[\cdot]$ denotes vector concatenation. W^{C_j} and b^{C_j} are trainable.

Given a tweet t , our loss for sentence classification model over m sentence classification subtasks $\{C_1, C_2 \dots C_m\}$ and Corresponding Event subtask is the following:

$$\begin{aligned} & Loss(t, y_{ces}, (y_1, y_2 \dots y_m)) \\ &= \lambda_2 CE_{Loss}(v_{ces}, y_{ces}) + \sum_{k=1}^m CE_{Loss}(h_f^{C_k}, y_k) \end{aligned}$$

Where CE_{Loss} is softmax cross entropy loss, y_{ces} is ground truth label for Corresponding event subtask and $(y_1, y_2 \dots y_m)$ are the labels for tweet t for the subtasks $\{S_1, S_2 \dots S_m\}$. We keep $\lambda_2 = 1$.

Preprocessing for sentence classification is done using ekphrasis library (Baziotis et al., 2017). We remove Emoji, URL, Email, punctuation and normalize text by word segmenting, lower-casing and word decontraction.

5 Experiments

All the experiments were performed using PyTorch (Paszke et al., 2019) and Hugging Face’s transformers (Wolf et al., 2019). We use git and wandb (Biewald, 2020) for experiment tracking. We use Adam optimizer (Kingma and Ba, 2014). The learning rate is $2e-5$. Slot-filling models are trained for 8 epochs and sentence classification model for 10 epochs. Average training time per epoch on Tesla P100 is ≈ 4 minutes for slot-filling, and ≈ 30 second for sentence classification.

A 70-30 split for train-valid set. The valid set is used to obtain the best threshold for each of the slot classification task over the grid $\{0.1, 0.2, \dots, 0.9\}$. We exclude labels with “No consensus” from our data.⁵

⁵As per the submission guidelines, some subtasks like opinion had their label classes merged. We incorporate these changes in our model.

Event	F1	P	R
Tested positive	.68	.80	.58
Tested negative	.66	.66	.67
Denied Testing	.65	.67	.64
Death	.69	.72	.67
Cure/Prevention	.63	.75	.53
Overall	.66	.73	.60

Table 3: Micro averaged scores on the held out test set for our final submission.

All the MLP have 1 hidden layer and 0.1 dropout. MLP_{S_j} has 4 hidden size, LeakyReLU activation (Maas et al., 2013) with 0.1 negative slope, rest of the MLP have 50 hidden size and Tanh activation.

6 Results

Our performance on the held-out test set is shown in Table 3 which **rank 1st position** in the task. We also independently rank 1st across 3 of the 5 events: ‘Denied Testing’, ‘Death’ and ‘Cure’.

Now we discuss our various experiments.

Slot-filling: We did a variety of experiments for slot-filling task. **Our (SF)** is our Slot-Filling Model from §4.1. **Our (SC) w/o pool** is our slot-filling model that uses the CT-Bert hidden representation of token $< E >$ to classify instead of doing an attention-weighted pooling. **Our (SC) w/o CES** is our slot-filling model without Corresponding Event subtask. **CT-Bert** and **Bert-large** are base-line models using CT-Bert and Bert-large instead of Bert-base.

Table 4 shows the performance of these models. There is a huge performance difference by using CT-Bert instead of Bert, demonstrate the benefits of domain specific pre-training. *Our (SF) w/o pool* and *Our (SF) w/o CES* outperforms CT-Bert demonstrating the importance of Corresponding Event task and attention-weighted pooling over slot-chunk respectively. *Our (SF)* using CT-Bert with corresponding event and attention-weighted pooling performs the best among these models.

Sentence level tasks: We experimented with various architectures for sentence level tasks. **Our (SC)** is our Sentence Classification architecture from §4.2. **Our (SC) w/o CES** is our Sentence Classification without Corresponding Event subtask. **Bert multitask** model predicts using the $[CLS]$ representation from Bert (Devlin et al., 2019). We also build an LSTM model (Hochreiter

Model	Micro F1	Macro F1
Our (SF)	.684	.558
Our (SF) w/o pool	.678	.557
Our (SF) w/o CES	.665	.552
CT-Bert	.662	.551
Bert (large)	.610	.529
Bert (baseline)	.612	.528

Table 4: Results slot-filling models on 70-30 train-valid. We report results on the valid set across all slot filling subtasks across the 5 events.

Model	Micro F1	Macro F1
Our (SE)	.788	.767
Our (SE) w/o CES	.777	.731
Bert multitask	.715	.612
LSTM multitask	.614	.543

Table 5: Results sentence classification models on 70-30 train-valid. We report results on the valid set across all sentence classification subtasks across the 5 events.

and Schmidhuber, 1997) with GloVe embedding (Pennington et al., 2014), and twitter-tokenization using WordTokenizers package (Kaushal et al., 2020).

Table 5 shows the performance of these architectures. Our (SC) outperforms others on macro F1 and micro F1, followed by Our (SC) w/o CES. This shows the benefits of including the Corresponding Event subtask. Using CT-Bert also helped over using Bert. And Bert-based models outperform LSTM by a very large margin demonstrating the superiority of these pretrained language models.

7 Conclusion and Future Work

In the paper we presented our system that bagged 1st position in the WNUT-2020 Shared Task-3 on Extracting COVID Entities from Twitter. We divided the event-specific subtasks into slot-filling and sentence classification subtasks, building separate architectures for the two. For both architectures, we used COVID-Twitter Bert, weighted-attention pooling over chunk-spans/sentence and fused logits and features from auxiliary corresponding event task.

There is a lot of scope of improvement for the subtasks with very few positive labels. Pretraining on relevant data (such as COVID-misinformation datasets for event cure) is good directions to explore.

Another direction would be to reduce the training and inference time of the slot-filling model by *not* enclosing the candidate chunk within special start $< E >$ and special end $< /E >$ tokens. We can instead use the proposed attention-weighted pooling over candidate slot chunks. This will reduce the number of Bert forward passes from $O(k)$ to $O(1)$, where k is the number of candidate chunks in a tweet.
